

Launch a Kubernetes Cluster

Nicolás Aversa

The screenshot displays the Amazon Elastic Kubernetes Service (EKS) console interface. The left sidebar shows the navigation menu with 'Amazon Elastic Kubernetes Service' at the top, followed by 'Clusters', 'Settings', 'Amazon EKS Anywhere', and 'Related services'. The main content area is titled 'nextwork-eks-cluster' and shows 'Nodes (3)' and 'Node groups (1)'. The 'Nodes' section contains a table with 3 nodes, all in a 'Ready' status. The 'Node groups' section shows a single node group named 'nextwork-nodegroup' with a desired size of 3.

Node name	Instance type	Compute	Managed by	Created	Status
ip-192-168-27-18.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready
ip-192-168-60-190.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready
ip-192-168-7-201.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready

Group name	Desired size	AMI release version	Launch template	Status
nextwork-nodegroup	3	1.31.5-20250317	eksctl-nextwork-eks-cluster-nodegroup-nextwork-nodegroup (1)	Active

Introducing Today's Project!

In this project, I will deploy a Kubernetes cluster using Amazon EKS to learn how to manage containerized applications in the cloud. I'll use EC2, CloudFormation, and IAM to create and access the cluster, and test its resilience.

What is Amazon EKS?

Amazon EKS (Elastic Kubernetes Service) is a managed service that simplifies running Kubernetes on AWS. It handles the setup, scaling, and maintenance of Kubernetes control planes, allowing you to focus on deploying and managing containerized applications. I used it to create a Kubernetes cluster with `eksctl`, set up a node group with scaling limits (min 1, max 3 nodes), automate infrastructure using CloudFormation, manage access with IAM roles, and test resilience by deleting nodes to observe Kubernetes' self-healing.

One thing I didn't expect

One thing I didn't expect in today's project was how straightforward it could be to create and manage Kubernetes clusters using Amazon EKS and eksctl. I was surprised by how much of the heavy lifting, like networking and resource provisioning, was automated by CloudFormation behind the scenes. It made the process much smoother than I anticipated, especially for someone new to Kubernetes!

This project took me...

This project took me 90 minutes. The part that took the longest was resolving the errors when creating the cluster with eksctl, as I needed to download it, and then set up the correct IAM roles and permissions to ensure everything worked smoothly.

I used `eksctl` to create an EKS cluster. The create cluster command I ran defined the cluster's name, nodegroup name, node type, number of nodes (min and max included), version and AWS region.

I initially ran into two errors while using eksctl. The first one was because I didn't have eksctl installed. The second one was because the default IAM role for my EC2 instance lacked permissions to create an EKS cluster.

[illegible]

eksctl and CloudFormation

CloudFormation helped create my EKS cluster because eksctl sets up a CloudFormation stack to automate the creation of all the necessary resources for the EKS cluster. It created VPC resources because it sets up a private, secure network for the containers to connect with each other and the internet while keeping the app private.

There was also a second CloudFormation stack for my node group, which is a group of EC2 instances that will run my containers. The difference between a cluster and node group is that a cluster is the entire Kubernetes environment (including the control plane and all nodes), while a node group is a subset of nodes within the cluster, grouped together with shared configurations for easier management.

Stacks (2)			
Filter by stack name Filter status: Active View nested			
Stack name	Status	Created time	Description
eksctl-nextwork-eks-cluster-nodegroup-nextwork-nodegroup	CREATE_COMPLETE	2025-03-21 20:11:01 UTC-0300	EKS Managed Nodes (SSH access: false) [created by eksctl]
eksctl-nextwork-eks-cluster-cluster	CREATE_COMPLETE	2025-03-21 20:00:57 UTC-0300	EKS cluster (dedicated VPC: true, dedicated IAM: true) [created and managed by eksctl]

The EKS console

I had to create an IAM access entry in order to get access to the nodes in my EKS cluster. An access entry is how we connect AWS IAM users with Kubernetes' Role-Based Access Control (RBAC), which is Kubernetes' system to manage access inside a cluster. I set it up by picking my IAM user's ARN and adding an AccessPolicy called AmazonEKSClusterAdminPolicy, choosing Cluster as the scope. This policy gives you full administrative rights over your EKS clusters.

It took 30 minutes to create my cluster. Since I'll create this cluster again in the next project of this series, maybe this process could be sped up if I ensure the IAM role and permissions are set up in advance.

Amazon Elastic Kubernetes Service > Clusters > nextwork-eks-cluster

Nodes (3) [Info](#)

Filter Nodes by property or value

Node name	Instance type	Compute	Managed by	Created	Status
ip-192-168-27-18.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready
ip-192-168-60-190.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready
ip-192-168-7-201.sa-east-1.compute.internal	t2.micro	Node group	nextwork-nodegroup	30 minutes ago	Ready

Node groups (1) [Info](#) [Edit](#) [Delete](#) [Add node group](#)

Node groups implement basic compute scaling through EC2 Auto Scaling groups.

Group name	Desired size	AMI release version	Launch template	Status
nextwork-nodegroup	3	1.31.5-20250317	eksctl-nextwork-eks-cluster-nodegroup-nextwork-nodegroup (1)	Active

EXTRA: Deleting nodes

Did you know you can find your EKS cluster's nodes in Amazon EC2? This is because when you create nodes in a Kubernetes cluster on AWS, each node is actually an EC2 instance! Kubernetes uses a generic term (node) because different cloud platforms use different cloud resources to be the node; in AWS, we use EC2 instances as our nodes.

Desired size is the number of nodes you want running in your node group. Minimum and maximum sizes are helpful for ensuring your application remains available and scalable. The minimum size ensures your app stays operational during low-demand periods by maintaining a baseline number of nodes, while the maximum size allows your node group to scale up during high-demand periods, preventing overloading. Together, these settings help Kubernetes automatically adjust the number of nodes to match your app's needs, balancing performance and cost.

When I deleted my EC2 instances, new instances were launched to replace the terminated ones. This is because Kubernetes automatically detects the change and launches new nodes to keep the cluster running at its desired state (3 nodes in my case).
